PYRROLOBENZODIAZEPINES

The present invention relates to pyrrolobenzodiazepines (PBDs), and in particular pyrrolobenzodiazepines useful in the synthesis of C2 substituted compounds.

Background to the invention

Some pyrrolobenzodiazepines (PBDs) have the ability to recognise and bond to specific sequences of DNA; the preferred sequence is PuG Pu. The first PBD antitumour antibiotic, anthramycin, was discovered in 1965 (Leimgruber, et al., *J. Am. Chem. Soc.*, **87**, 5793-5795 (1965); Leimgruber, et al., *J. Am. Chem. Soc.*, **87**, 5791-5793 (1965)). Since then, a number of naturally occurring PBDs have been reported, and over 10 synthetic routes have been developed to a variety of analogues (Thurston, et al., *Chem. Rev.* **1994**, 433-465 (1994)). Family members include abbeymycin (Hochlowski, et al., *J. Antibiotics*, **40**, 145-148 (1987)), chicamycin (Konishi, et al., *J. Antibiotics*, **37**, 200-206 (1984)), DC-81 (Japanese Patent 58-180 487; Thurston, et al., *Chem. Brit.*, **26**, 767-772 (1990); Bose, et al., *Tetrahedron*, **48**, 751-758 (1992)), mazethramycin (Kuminoto, et al., *J. Antibiotics*, **33**, 665-667 (1980)), neothramycins A and B (Takeuchi, et al., *J. Antibiotics*, **29**, 93-96 (1976)), porothramycin (Tsunakawa, et al., *J. Antibiotics*, **41**, 1366-1373 (1988)), prothracarcin (Shimizu, et al., *J. Antibiotics*, **29**, 2492-2503 (1982); Langley and Thurston, *J. Org. Chem.*, **52**, 91-97 (1987)), sibanomicin (DC-102) (Hara, et al., *J. Antibiotics*, **41**, 702-704 (1988); Itoh, et al., *J. Antibiotics*, **41**, 1281-1284 (1988)), sibiromycin (Leber, et al., *J. Am. Chem. Soc.*, **110**, 2992-2993 (1988)) and tomamycin (Arima, et al., *J. Antibiotics*, **25**, 437-444 (1972)). PBDs are of the general structure:

They differ in the number, type and position of substituents, in both their aromatic A rings and pyrrolo C rings, and in the degree of saturation of the C ring. In the B-ring there is either an imine (N=C), a carbinolamine (NH-CH(OH)), or a carbinolamine methyl ether (NH-CH(OMe)) at the N10-C11 position which is the electrophilic centre responsible for alkylating DNA. All of the known natural products have an (S)-configuration at the chiral C11a position which provides them with a right-handed twist when viewed from the C ring towards the A ring. This gives them the appropriate three-dimensional shape for isohelicity with the minor groove of B-form DNA, leading to a snug fit at the binding site (Kohn, In *Antibiotics III*. Springer-Verlag, New York, pp. 3-11 (1975); Hurley and Needham-VanDevanter, *Acc. Chem. Res.*, **19**, 230-237 (1986)). Their ability to form an adduct in the minor groove, enables them to interfere with DNA processing, hence their use as antitumour agents.

The present inventors have previously disclosed, in PCT/GB2003/004963, cytotoxic compounds having an aryl group at the C2 position, for example:

The synthesis of these compounds was achieved via the following intermediate:

whose synthesis was described in detail in WO 00/12508. This method involves a reduction as a deprotection step, which can lead to overreduction of the compound which is not desirable. Also, with certain C2 groups, the reduction step does not proceed at all.

The following intermediate has also been disclosed:

but its synthesis has proved difficult and only proceeds in low yield.

Disclosure of the invention

The present inventors have developed a key intermediate for the production of C2 substituted PBDs, which has a leaving group at the C2 position, a carbamate protecting group at the N10 position and a protected hydroxy group at the C11 position.

In a first aspect, the present invention comprises a compound with the formula I:

wherein:

R⁶ and R⁹ are independently selected from H, R, OH, OR, SH, SR, NH₂, NHR, NRR', nitro, Me₃Sn and halo;

where R and R' are independently selected from optionally substituted C₁₋₁₂ alkyl, C₃₋₂₀ heterocyclyl and C₅₋₂₀ aryl groups; R⁷ and R⁸ are independently selected from H, R, OH, OR, SH, SR, NH₂, NHR, NHRR', nitro, Me₃Sn and halo, or the compound is a dimer with each monomer being of formula (I), where the R⁷ groups or R⁸ groups of each monomers form together a dimer bridge having the formula -X-R"-X- linking the monomers, where R" is a C₃₋₁₂ alkylene group, which chain may be interrupted by one or more heteroatoms, e.g. O, S, NH, and/or aromatic rings, e.g. benzene or pyridine, and each X is independently selected from O, S, or NH; or any pair of adjacent groups from R⁶ to R⁹ together form a group -O-(CH₂)_p-O-, where p is 1 or 2; R¹⁰ is a carbamate-based nitrogen protecting group; R¹¹ is an oxygen protecting group; and R² is a labile leaving group.

In a second aspect, the present invention comprises a method of synthesising a compound of formula I as defined in the first aspect of the invention from a compound of formula IIa:

wherein R⁶, R⁷, R⁸, R⁹, R¹⁰ and R¹¹ are as defined in the first aspect;

R¹² and R¹³ together form =O.

It is preferred that the compound of formula IIa is synthesised from a compound of formula IIb:

wherein R^6 , R^7 , R^8 , R^9 , R^{10} and R^{11} are as defined in the first aspect;

R^{12} is $O-R^{14}$, and R^{13} is H, where R^{14} is an oxygen protecting group which is orthogonal to R^{11} .

5

In a third aspect, the present invention comprises a method of synthesising a compound of formula III:

or a solvate thereof, from a compound of formula I as defined in the first aspect, wherein R^6 , R^7 , R^8 , R^9 are as defined in the first aspect;

R^{10} is as defined in the first aspect and R^{16} is either $O-R^{11}$, wherein R^{11} is as defined in the first aspect, or OH, or R^{10} and R^{16} together form a double bond between N10 and C11; and

R^{15} is R.

Further aspects of the present invention relate to novel compounds of formula III (including solvates thereof when R^{10} and R^{16} form a double bond between N10 and C11, and pharmaceutical salts thereof), their use in methods of therapy (particularly in treating proliferative diseases), pharmaceutical compositions comprising these, and their use in the manufacture of a medicament for the treatment of a proliferative disease.

Definitions

Carbamate-based nitrogen protecting groups

Carbamate-based nitrogen protecting groups are well known in the art, and have the following structure:

wherein R'¹⁰ is R as defined above. A large number of suitable groups are described on pages 503 to 549 of Greene, T.W. and Wuts, G.M., *Protective Groups in Organic Synthesis*, 3rd Edition, John Wiley & Sons, Inc., 1999, which is incorporated herein by reference.

Particularly preferred protecting groups include Troc, Teoc, Fmoc, BOC, Doc, Hoc, TcBOC, 1-Adoc and 2-Adoc.

Those protecting groups which can be removed with palladium catalysis are not preferred, e.g. Alloc.

Also suitable for use in the present invention are nitrogen protecting group which can be removed *in vivo* (e.g. enzymatically, using light) as described in WO 00/12507, which is incorporated herein by reference. Examples of these protecting groups include:

, which is nitroreductase labile (e.g. using ADEPT/GDEPT);

and

, which are photolabile; and

which is glutathione labile (e.g. using NPEPT).

Oxygen protecting groups

Oxygen protecting groups are well known in the art. A large number of suitable groups are described on pages 23 to 200 of Greene, T.W. and Wuts, G.M., *Protective Groups in Organic Synthesis*, 3rd Edition,

John Wiley & Sons, Inc., 1999, which is incorporated herein by reference.

Classes of particular interest include silyl ethers, methyl ethers, alkyl ethers, benzyl ethers, esters, benzoates, carbonates, and sulfonates.

Preferred oxygen protecting groups include TBS, THP for the C11 oxygen atom, and methyl ester for the C2 oxygen atom (where present).

As mentioned above the oxygen protecting group R^{14} should be orthogonal to the oxygen protecting group R^{11} . Protecting groups which are orthogonal to one another may each be removed using reagents or conditions which do not remove the other protecting group.

It may also be preferred that any protecting groups used during the synthesis and use of compounds of formula I are orthogonal to one another. However, it is often not necessary, but may be desirable, for the carbamate-based nitrogen protecting group and R^{11} to be orthogonal to one another, depending on whether the compound of formula III is to be used with the nitrogen protecting group in place.

Labile leaving groups

Labile leaving groups suitable for use in the present invention are in particular those amenable to palladium catalysed coupling, for example using Suzuki or Stille coupling. Suitable groups include mesylate ($-\text{OSO}_2\text{CH}_3$), $-\text{OSO}_2(\text{C}_n\text{F}_{2n+1})$ where $n=0,1$ or 4 , $-\text{OSO}_2-\text{R}^s$ where R^s is an optionally substituted phenyl group (e.g. 4-Me-Ph, tosylate), I, Br and Cl. More preferred are $-\text{OSO}_2(\text{C}_n\text{F}_{2n+1})$ where $n=0,1$ or 4 , I, Br and Cl, with triflate ($-\text{OSO}_2\text{CF}_3$) and Br being the most preferred.

10 The term "proliferative disease" pertains to an unwanted or uncontrolled cellular proliferation of excessive or abnormal cells which is undesired, such as, neoplastic or hyperplastic growth, whether *in vitro* or *in vivo*.

15 Examples of proliferative conditions include, but are not limited to, benign, pre-malignant, and malignant cellular proliferation, including but not limited to, neoplasms and tumours (e.g. histocytoma, glioma, astrocyoma, osteoma), cancers (e.g. lung
20 cancer, small cell lung cancer, gastrointestinal cancer, bowel cancer, colon cancer, breast carcinoma, ovarian carcinoma, prostate cancer, testicular cancer, liver cancer, kidney cancer, bladder cancer, pancreas cancer, brain cancer, sarcoma, osteosarcoma, Kaposi's sarcoma, melanoma), leukemias, psoriasis, bone diseases,
25 fibroproliferative disorders (e.g. of connective tissues), and atherosclerosis.

Any type of cell may be treated, including but not limited to, lung, gastrointestinal (including, e.g. bowel, colon), breast
30 (mammary), ovarian, prostate, liver (hepatic), kidney (renal), bladder, pancreas, brain, and skin.

Methods of Treatment

35 As described above, the present invention provide the use of a compound of formula III in a method of therapy. Also provided is a method of treatment, comprising administering to a subject in need

of treatment a therapeutically-effective amount of a compound of formula III, preferably in the form of a pharmaceutical composition, which is the third aspect of the present invention. The term "therapeutically effective amount" is an amount sufficient to show benefit to a patient. Such benefit may be at least amelioration of at least one symptom. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage, is within the responsibility of general practitioners and other medical doctors.

A compound may be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated. Examples of treatments and therapies include, but are not limited to, chemotherapy (the administration of active agents, including, e.g. drugs; surgery; and radiation therapy. If the compound of formula III bears a carbamate-based nitrogen protecting group which may be removed *in vivo*, then the methods of treatment described in WO 00/12507 (ADEPT, GDEPT and PDT) may be used.

Pharmaceutical compositions according to the present invention, and for use in accordance with the present invention, may comprise, in addition to the active ingredient, i.e. a compound of formula III, a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g. cutaneous, subcutaneous, or intravenous.

Pharmaceutical compositions for oral administration may be in tablet, capsule, powder or liquid form. A tablet may comprise a solid carrier or an adjuvant. Liquid pharmaceutical compositions generally comprise a liquid carrier such as water, petroleum,

animal or vegetable oils, mineral oil or synthetic oil.
 Physiological saline solution, dextrose or other saccharide
 solution or glycols such as ethylene glycol, propylene glycol or
 polyethylene glycol may be included. A capsule may comprise a
 solid carrier such a gelatin.

For intravenous, cutaneous or subcutaneous injection, or injection
 at the site of affliction, the active ingredient will be in the
 form of a parenterally acceptable aqueous solution which is
 pyrogen-free and has suitable pH, isotonicity and stability. Those
 of relevant skill in the art are well able to prepare suitable
 solutions using, for example, isotonic vehicles such as Sodium
 Chloride Injection, Ringer's Injection, Lactated Ringer's
 Injection. Preservatives, stabilisers, buffers, antioxidants
 and/or other additives may be included, as required.

Includes Other Forms

Unless otherwise specified, included in the above are the well
 known ionic, salt, solvate, and protected forms of these
 substituents. For example, a reference to carboxylic acid ($-\text{COOH}$)
 also includes the anionic (carboxylate) form ($-\text{COO}^-$), a salt or
 solvate thereof, as well as conventional protected forms.
 Similarly, a reference to an amino group includes the protonated
 form ($-\text{N}^+\text{HR}^1\text{R}^2$), a salt or solvate of the amino group, for example,
 a hydrochloride salt, as well as conventional protected forms of an
 amino group. Similarly, a reference to a hydroxyl group also
 includes the anionic form ($-\text{O}^-$), a salt or solvate thereof, as well
 as conventional protected forms.

Isomers, Salts and Solvates

Certain compounds may exist in one or more particular geometric,
 optical, enantiomeric, diastereomeric, epimeric, atropic,
 stereoisomeric, tautomeric, conformational, or anomeric forms,
 including but not limited to, cis- and trans-forms; E- and Z-forms;
 c-, t-, and r- forms; endo- and exo-forms; R-, S-, and meso-forms;
 D- and L-forms; d- and l-forms; (+) and (-) forms; keto-, enol-,

and enolate-forms; syn- and anti-forms; synclinal- and anticlinal-forms; α - and β -forms; axial and equatorial forms; boat-, chair-, twist-, envelope-, and halfchair-forms; and combinations thereof, hereinafter collectively referred to as "isomers" (or "isomeric forms").

Preferably compounds of the present invention have the following stereochemistry at the C11 position:

Note that, except as discussed below for tautomeric forms, specifically excluded from the term "isomers", as used herein, are structural (or constitutional) isomers (i.e. isomers which differ in the connections between atoms rather than merely by the position of atoms in space). For example, a reference to a methoxy group, $-OCH_3$, is not to be construed as a reference to its structural isomer, a hydroxymethyl group, $-CH_2OH$. Similarly, a reference to ortho-chlorophenyl is not to be construed as a reference to its structural isomer, meta-chlorophenyl. However, a reference to a class of structures may well include structurally isomeric forms falling within that class (e.g. C_{1-7} alkyl includes n-propyl and iso-propyl; butyl includes n-, iso-, sec-, and tert-butyl; methoxyphenyl includes ortho-, meta-, and para-methoxyphenyl).

The above exclusion does not pertain to tautomeric forms, for example, keto-, enol-, and enolate-forms, as in, for example, the following tautomeric pairs: keto/enol (illustrated below), imine/enamine, amide/imino alcohol, amidine/amidine, nitroso/oxime, thioketone/enethiol, N-nitroso/hydroxyazo, and nitro/aci-nitro.

Note that specifically included in the term "isomer" are compounds with one or more isotopic substitutions. For example, H may be in any isotopic form, including ^1H , ^2H (D), and ^3H (T); C may be in any isotopic form, including ^{12}C , ^{13}C , and ^{14}C ; O may be in any isotopic form, including ^{16}O and ^{18}O ; and the like.

Unless otherwise specified, a reference to a particular compound includes all such isomeric forms, including (wholly or partially) racemic and other mixtures thereof. Methods for the preparation (e.g. asymmetric synthesis) and separation (e.g. fractional crystallisation and chromatographic means) of such isomeric forms are either known in the art or are readily obtained by adapting the methods taught herein, or known methods, in a known manner.

Unless otherwise specified, a reference to a particular compound also includes ionic, salt, solvate, and protected forms of thereof, for example, as discussed below.

It may be convenient or desirable to prepare, purify, and/or handle a corresponding salt of the active compound, for example, a pharmaceutically-acceptable salt. Examples of pharmaceutically acceptable salts are discussed in Berge, et al., *J. Pharm. Sci.*, **66**, 1-19 (1977).

For example, if the compound is anionic, or has a functional group which may be anionic (e.g. $-\text{COOH}$ may be $-\text{COO}^-$), then a salt may be formed with a suitable cation. Examples of suitable inorganic cations include, but are not limited to, alkali metal ions such as Na^+ and K^+ , alkaline earth cations such as Ca^{2+} and Mg^{2+} , and other cations such as Al^{+3} . Examples of suitable organic cations include, but are not limited to, ammonium ion (i.e. NH_4^+) and substituted ammonium ions (e.g. NH_3R^+ , NH_2R_2^+ , NHR_3^+ , NR_4^+). Examples of some suitable substituted ammonium ions are those derived from: ethylamine, diethylamine, dicyclohexylamine, triethylamine, butylamine, ethylenediamine, ethanolamine, diethanolamine,

piperazine, benzylamine, phenylbenzylamine, choline, meglumine, and tromethamine, as well as amino acids, such as lysine and arginine. An example of a common quaternary ammonium ion is $N(CH_3)_4^+$.

5 If the compound is cationic, or has a functional group which may be cationic (e.g. $-NH_2$ may be $-NH_3^+$), then a salt may be formed with a suitable anion. Examples of suitable inorganic anions include, but are not limited to, those derived from the following inorganic acids: hydrochloric, hydrobromic, hydroiodic, sulfuric, sulfurous, 10 nitric, nitrous, phosphoric, and phosphorous.

Examples of suitable organic anions include, but are not limited to, those derived from the following organic acids:

2-acetoxybenzoic, acetic, ascorbic, aspartic, benzoic, 15 camphorsulfonic, cinnamic, citric, edetic, ethanedisulfonic, ethanesulfonic, fumaric, glucheptonic, gluconic, glutamic, glycolic, hydroxymaleic, hydroxynaphthalene carboxylic, isethionic, lactic, lactobionic, lauric, maleic, malic, methanesulfonic, mucic, oleic, oxalic, palmitic, pamoic, pantothenic, phenylacetic, 20 phenylsulfonic, propionic, pyruvic, salicylic, stearic, succinic, sulfanilic, tartaric, toluenesulfonic, and valeric. Examples of suitable polymeric organic anions include, but are not limited to, those derived from the following polymeric acids: tannic acid, carboxymethyl cellulose.

25 It may be convenient or desirable to prepare, purify, and/or handle a corresponding solvate of the active compound. The term "solvate" is used herein in the conventional sense to refer to a complex of solute (e.g. active compound, salt of active compound) and solvent. 30 If the solvent is water, the solvate may be conveniently referred to as a hydrate, for example, a mono-hydrate, a di-hydrate, a tri-hydrate, etc.

Solvates of particular relevance to the present invention are those 35 where the solvent adds across the imine bond of the PBD moiety,

which is illustrated below where the solvent is water or an alcohol ($R^A\text{OH}$, where R^A is an ether substituent as described above):

These forms can be called the carbinolamine and carbinolamine ether forms of the PBD. The balance of these equilibria depend on the conditions in which the compounds are found, as well as the nature of the moiety itself.

In general any nucleophilic solvent is capable of forming such solvates as illustrated above for hydroxylic solvents. Other nucleophilic solvents include thiols and amines.

These solvates may be isolated in solid form, for example, by lyophilisation.

General synthetic routes

The synthesis of PBD compounds is extensively discussed in WO 00/12508, which discussion is incorporated herein by reference.

As discussed in that patent application, a key step in a preferred route to PBDs is a cyclisation to produce the B-ring, involving generation of an aldehyde (or functional equivalent thereof) at what will be the 11-position, and attack thereon by the Pro-N10-nitrogen:

wherein the substituents are as defined in the second aspect of the invention. The "masked aldehyde" -CPQ may be an acetal or

thioacetal, in which case the cyclisation involves unmasking. Alternatively, it may be an alcohol -CHOH, in which case the reaction involves oxidation, e.g. by means of TPAP, TEMPO or DMSO (Swern oxidation).

5

In this reaction, R^{12} is preferably $O-R^{14}$, i.e. a protected hydroxy group, and R^{13} is H.

10

The masked aldehyde compound can be produced by condensing a corresponding 2,4-substituted pyrrolidine with a 2-nitrobenzoic acid:

15

The nitro group can then be reduced to $-NH_2$ and protected by reaction with a suitable agent, e.g. a chloroformate, which provides the removable nitrogen protecting group in the compound of formula IV.

20

A process involving the oxidation-cyclization procedure is illustrated in scheme 1 (an alternative type of cyclisation will be described later with reference to scheme 2).

Scheme 1

Exposure of the alcohol (B) (in which the Pro-N10-nitrogen is generally protected as carbamate) to tetrapropylammonium perruthenate (TPAP)/N-methylmorpholine N-oxide (NMO) over A4 sieves results in oxidation accompanied by spontaneous B-ring closure to afford the desired product **IV**. The TPAP/NMO oxidation procedure is found to be particularly convenient for small scale reactions while the use of DMSO-based oxidation methods, particularly Swern oxidation, proves superior for larger scale work (e.g. > 1 g). A particularly preferred oxidising agent is (diacetoxyiodo)benzene (1.1 eq) and TEMPO (0.1 eq) dissolved in CH_2Cl_2 .

The uncyclized alcohol (B) may be prepared by the reaction of a nitrogen protection reagent of formula D, which is preferably a chloroformate or acid chloride, to a solution of the amino alcohol C, generally in solution, generally in the presence of a base such as pyridine (preferably 2 equivalents) at a moderate temperature

(e.g. at 0°C). Under these conditions little or no O-acylation is usually observed.

The key amino alcohol C may be prepared by reduction of the corresponding nitro compound E, by choosing a method which will leave the rest of the molecule intact. Treatment of E with tin (II) chloride in a suitable solvent, e.g. refluxing methanol, generally affords, after the removal of the tin salts, the desired product in high yield.

Exposure of E to hydrazine/Raney nickel avoids the production of tin salts and may result in a higher yield of C, although this method is less compatible with the range of possible C and A-ring substituents. For instance, if there is C-ring unsaturation (either in the ring itself, or in R₂ or R₃), this technique may be unsuitable. Another suitable means of reduction would be catalytic hydrogenation using palladium on carbon as a catalyst.

The nitro compound of formula E may be prepared by coupling the appropriate o-nitrobenzoyl chloride to a compound of formula F, e.g. in the presence of K₂CO₃ at -25°C under a N₂ atmosphere. Compounds of formula F can be readily prepared, for example by olefination of the ketone derived from L-trans-hydroxy proline. The ketone intermediate can also be exploited by conversion to the enol triflate for use in palladium mediated coupling reactions.

The o-nitrobenzoyl chloride is synthesised from the o-nitrobenzoic acid (or alkyl ester after hydrolysis) of formula G, which itself is prepared from the vanillic acid (or alkyl ester) derivative H. Many of these are commercially available and some are disclosed in Althuis, T.H. and Hess, H.J., *J. Medicinal Chem.*, 20(1), 146-266 (1977).

Alternative Cyclisation (Scheme 2)

Scheme 2

5 In scheme 1, the final or penultimate step was an oxidative cyclisation. An alternative, using thioacetal coupling, is shown in scheme 2. Mercury-mediated unmasking causes cyclisation to the protected PBD compound IV.

10 The thioacetal compound may be prepared as shown in scheme 2: the thioacetal protected C-ring [prepared via a literature method: Langley, D.R. & Thurston, D.E., *J. Organic Chemistry*, 52, 91-97 (1987)] is coupled to the o-nitrobenzoic acid (or alkyl ester after hydrolysis) (G) using a literature procedure. The resulting nitro compound cannot be reduced by hydrogenation, because of the

15 thioacetal group, so the tin(II) chloride method is used to afford

the amine. This is then N-protected, e.g., by reaction with a chloroformate or acid chloride, such as 2,2,2-trichloroethylchloroformate.

- 5 Acetal-containing C-rings can be used as an alternative in this type of route with deprotection involving other methods, including the use of acidic conditions.

Dimer Synthesis (Scheme 3)

G'

Scheme 3

PBD dimers may be synthesized using the strategy developed for the synthesis of the protected PBD monomers. The synthesis routes illustrated in scheme 3 show compounds when the dimer linkage is of the formula $-O-(CH_2)_n-O-$. The step of dimer formation is normally

carried out to form a bis(nitro acid) G'. This compound can then be treated as compound G in either scheme 1 or scheme 2 above.

5 The bis(nitro acid) G' may be obtained by nitrating (e.g. using 70% nitric acid) the bis(carboxylic acid). This can be synthesised by alkylation of two equivalents of the relevant benzoic acid with the appropriate diiodoalkane under basic conditions. Many benzoic acids are commercially available and others can be synthesised by conventional methods. Alternatively, the relevant benzoic acid
10 esters can be joined together by a Mitsunobu etherification with an appropriate alkanediol, followed by nitration, and then hydrolysis (not illustrated).

15 An alternative synthesis of the bis(nitro acid) involves oxidation of the bis(nitro aldehyde), e.g. with potassium permanganate. This can be obtained in turn by direct nitration of the bis(aldehyde), e.g. with 70% HNO₃. Finally, the bis(aldehyde) can be obtained via the Mitsunobu etherification of two equivalents of the benzoic aldehyde with the appropriate alkanediol.

20 *Alternative routes to PBDs*

Alternative methods of synthesising N10 protected PBDs are disclosed in co-pending application GB0321295.8 (filed 11 September 2003), which describes the use of isocyanate intermediates.

Formation of Compound of formula I

Following cyclisation to form the B-ring, the C11-alcohol IV is then preferably re-protected, by conventional means to provide IIb.

5 For example, if R¹¹ is TBS, the protection can take place by reacting IV with TBSOTf and 2,6-lutidine. Cleavage of the C2-protecting group from IIb then provides the C2 alcohol. For example, where the C2 protecting group (R¹⁴) is acyl, this deprotection may be performed by addition of an aqueous solution of

10 K₂CO₃.

This reprotection at the C11 position and deprotection of the C2 alcohol allows subsequent reaction of selectively the C2 alcohol position leaving the C11 position unaffected.

15 The C2-alcohol may then be oxidized to the ketone IIb. Preferably this oxidation is performed under Swern conditions, in good yield. However, other oxidation methods involving TPAP or the Dess Martin reagent also provide the ketone in good yield.

20 If R² in the compound of formula I is -OSO₂CH₃, -OSO₂(C_nF_{2n+1}) where n=0,1 or 4, or -OSO₂R^s, then the conversion from IIb may be achieved by treatment with the appropriate anhydride. For example, if R² is triflate that reaction with trifluoromethanesulfonic anhydride in DCM in the presence of pyridine.

If R^2 in the compound of formula I is $-I$ or $-Br$, then the conversion from **IIb** may be achieved by reaction with hydrazine and iodine or bromine respectively.

- 5 If R^2 in the compound of formula I is $-Cl$, then the conversion from **IIb** may be achieved by reaction with a phosphorous oxychloride (e.g. $POCl_3$).

Synthesis of compounds of formula III

10 This compound of formula I may be reacted under a variety of conditions to yield PBD precursor molecules with pendant groups coupled at the C2 position **IIIc**.

- 15 In particular, the use of palladium catalysed coupling is preferred, such as Suzuki, Stille and Heck coupling. The palladium catalyst may be any suitable catalyst, for example $Pd(PPh_3)_4$, $Pd(OCOCH_3)_2$, $PdCl_2$, $Pd(dba)_3$. The compounds which are coupled may be any suitable reactant, e.g. for Heck, alkenes with an sp^2 H; for Stille, organostannanes; and for Suzuki, organoboron derivatives.
- 20

In a preferred aspect of the invention, the coupling may be performed under microwave conditions. Typically, the palladium catalyst, such as $Pd(PPh_3)_4$, is solid supported, for example on polystyrene, to facilitate work-up and allow potential recycling of

25

catalyst. Unreacted boronic acid can be sequestered following complete consumption of triflate using PS-DEAM, with a phase separator cartridge being used to isolate the coupling product. Such a method allows for the parallel synthesis of more than one (e.g. up to 10, 20 or 30) compound at the same time.

The imine bond in the compound of formula IIIc can be unprotected by standard methods to yield the unprotected compound IIIa (which may be in its carbinolamine or carboinolamine ether form , depending on the solvents used). For example if R^{10} is Alloc, then the deprotection is carried using palladium to remove the N10 protecting group, followed by the elimination of water. If R^{10} is Troc, then the deprotection is carried out using a Cd/Pb couple to yield the compound of formula IIIa.

If the nitrogen protecting group (R^{10}) is such that the desired end product still contains it, e.g. if it is removable *in vivo*, then the compound of formula IIIb may be synthesised by removal of the oxygen protecting groups under suitable conditions.

 triflate 13 (193 mg, 0.13 mmol), LiCl (34 mg, 0.80 mmol, 6.0 eq)
 and tributyl(phenylethynyl)tin (0.14 mL, 157 mg, 0.40 mmol, 3.0 eq)

 2.5 h when TLC showed the complete consumption of the starting
 material. After cooling to room temperature, excess solvent was
 removed and the residue was dissolved in DCM (20 mL), followed by
 washin with 10 % NH₄OH (20 mL). The aqueous layer was extracted
 with DCM (3 x 20 mL), and the organic extracts were combined,
 washed with brine (50 mL) and dried (MgSO₄). Filtration and
 evaporation of solvent afforded the crude product which was
 purified by flash column chromatography (80:20 v/v hexane/EtOAc) to

A solution of K_2CO_3 (732 mg, 5.30 mmol; 1.0 Equiv.) in water (15 mL) was added to a stirred solution of **24** (3.32 g, 5.30 mmol, 1.0 Equiv.) in MeOH (15 mL) and THF (5 mL). The mixture was stirred at room temperature for 5 h and then excess solvent was removed by rotary evaporation at reduced pressure. The remaining aqueous residue was neutralised to pH 7 with 1N HCl and extracted with EtOAc (4 x 30 mL). The organic layers were combined, washed with brine (50 mL), dried ($MgSO_4$), filtered and concentrated *in vacuo*. Pyridine (1.71 mL; 21.17 mmol; 7 Equiv.) and trifluoromethanesulfonic anhydride (3.56 mL; 21.17 mmol; 7 Equiv) were added to a stirred solution of 27 (1.76 g, 3.02 mmol; 1 Equiv.) in dry CHCl_3 (50 mL) at 0-5 °C (ice bath). (i) A solution of triethylamine (0.12 mL, 6 equiv.) in water (0.2 mL) and ethanol (1.0 mL) was poured into a stirred solution of **27** (100 mg, 0.14 mmol, 1 Equiv.) in toluene (1.0 mL) in an EmrysTM Process vial. To the solution was added the appropriate boronic acid (1.07 equiv.) and polystyrene triphenylphosphine palladium (0) PS-PPh₃Pd (15 mg, 0.0014 mmol, 0.01 Equiv). The vial was sealed with a ResealTM septum, and the suspension then irradiated at 100°C for 20 minutes under microwave radiation using an EmrysTM Optimizer Microwave Station when TLC showed absence of starting material. N,N-diethanolaminomethyl polystyrene PS-DEAM (87.5 mg, 0.14 mmol, 1.0 equiv. [13 equiv. on boronic acid excess]) was added to the reaction, and the suspension was irradiated at 100°C for 10 minutes under microwave radiation (as above). Water (3 mL) was added to the reaction, and the suspension shaken for 10 minutes. The mixture was then transferred to a phase separator (PS) cartridge fitted with a selectively permeable frit pre-conditioned with CH₂Cl₂ (3 mL) and coupled to a Na₂SO₄ cartridge. Extraction with CH₂Cl₂ (3 x 5 mL), followed by concentration *in vacuo* yielded an oil which was redissolved in THF (1.5 mL) and 1N ammonium acetate (1.5 mL).

(ii) To the mixture resulting from the previous step was added 10% Cd/Pb (140 mg, 1.12 mmol, 8.0 Equiv.) while vigorously stirring and the reaction was kept for 1 hour at room temperature when TLC showed absence of starting material. The mixture was poured into an identical PS cartridge pre-conditioned with CH₂Cl₂ (3 mL) and coupled to a Na₂SO₄ cartridge. Extraction with CH₂Cl₂ (3 x 5 mL) followed by concentration *in vacuo* gave an oil which was subjected

to flash chromatography (EtOAc:Hexane 1:1) afforded the desired compounds, which are listed below.

Example 9: Determination of *In Vitro* Cytotoxicity

15 K562 human chronic myeloid leukaemia cells were maintained in RPM1 1640 medium supplemented with 10% fetal calf serum and 2 mM glutamine at 37°C in a humidified atmosphere containing 5% CO₂ and were incubated with a specified dose of drug for 1 hour at 37°C in the dark. The incubation was terminated by centrifugation (5 min, 300 g) and the cells were washed once with drug-free medium. Following the appropriate drug treatment, the cells were
20 transferred to 96-well microtiter plates (10⁴ cells per well, 8 wells per sample). Plates were then kept in the dark at 37°C in a

humidified atmosphere containing 5% CO₂. The assay is based on the ability of viable cells to reduce a yellow soluble tetrazolium salt, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT, Aldrich-Sigma), to an insoluble purple formazan precipitate. Following incubation of the plates for 4 days (to allow control cells to increase in number by approximately 10 fold), 20 μ L of MTT solution (5 mg/mL in phosphate-buffered saline) was added to each well and the plates further incubated for 5 h. The plates were then centrifuged for 5 min at 300 g and the bulk of the medium pipetted from the cell pellet leaving 10-20 μ L per well. DMSO (200 μ L) was added to each well and the samples agitated to ensure complete mixing. The optical density was then read at a wavelength of 550 nm on a Titertek Multiscan ELISA plate reader, and a dose-response curve was constructed. For each curve, an IC₅₀ value was read as the dose required to reduce the final optical density to 50% of the control value.
